provide models that could be used by do it yourselfers and also can be used to provide understanding of the background issues so that one can do a better job of working with the proprietary algorithms of the software vendors in this book we strive to provide models that capture many of the tails faced by rms operating in a modern supply chain but we stop short of proposing models for economic analysis of the entire multi player chain in other words we produce models that are useful for planning within a supply chain rather than models for planning the supply chain the usefulness of the models is enhanced greatly by the fact that they have been implemented in computer modeling languages implementations are shown in chapter 7 which allows solutions to be implemented on a computer a reasonable question is why write the book now it is a combination of opportunities that have recently become available the availability of modeling languages and computers that provide the opportunity to make practical use of the models that we develop meanwhile software companies are providing software for optimized production planning in a supply chain the opportunity to make use of such software gives rise to a

program management concerns the long term planning coordination and control of major technological engineering scientific and or developmental activities in general programs tend to be exceptionally large consisting of several parallel or sequential projects or groups of projects while many of the approaches developed for projects have been used in program management there are critical differences between programs and projects a key difference is the magnitude of programs both in program duration and number of tasks to be coordinated in addition project parameters are driven by program decisions while a large number of modeling efforts have focused at the project level very little optimization literature deals directly with aspects of initial program design and development this thesis effort looks at the application of optimization techniques to the initial design and development of multi project programs the classic work breakdown structure is used as a framework for dantzig wolfe decomposition to provide an aggregate model for investigating the effects of funding levels resource allocation and program durations

automated planning is known to be computationally hard in the general case propositional planning is pspace complete and first order planning is undecidable one method for analyzing the computational complexity of planning is to study restricted subsets of planning instances with the aim of differentiating instances with varying complexity we use

this methodology for studying the computational complexity of planning finding new tractable i.e. polynomial time solvable problems has been a particularly important goal for researchers in the area the reason behind this is not only to differentiate between easy and hard planning instances but also to use polynomial time solvable instances in order to construct better heuristic functions and improve planners we identify a new class of tractable cost optimal planning instances by restricting the causal graph we study the computational complexity of oversubscription planning such as the net benefit problem under various restrictions and reveal strong connections with classical planning inspired by this we present a method for compiling oversubscription planning problems into the ordinary plan existence problem we further study the parameterized complexity of cost optimal and net benefit planning under the same restrictions and show that the choice of numeric domain for the action costs has a great impact on the parameterized complexity we finally consider the parameterized complexity of certain problems related to partial order planning in some applications less restricted plans than total order plans are needed therefore a partial order plan is being used instead when dealing with partial order plans one important question is how to achieve optimal partial order plans i.e. having the highest degree of freedom according to some notion of flexibility we study several optimization problems for partial order plans such as finding a minimum deordering or reordering and finding the minimum parallel execution length

doctoral thesis dissertation from the year 2017 in the subject engineering robotics university of technology sydney course philosophy degree language english abstract the application and use of robots in various areas of human life have been growing since the advent of robotics and as a result an increasing number of collaboration tasks are taking place during

a collaboration humans and robots typically interact through a physical medium and it is likely that as more interactions occur the possibility for humans to experience pain will increase it is therefore of primary importance that robots should be capable of understanding the human concept of pain and to react to that understanding however studies reveal that the concept of human pain is strongly related to the complex structure of the human nervous system and the concept of mind which includes concepts of self awareness and consciousness thus developing an appropriate concept of pain for robots must incorporate the concepts of self awareness and consciousness our approach is firstly to acquire an appropriate concept of self awareness as the basis for a robot framework secondly it is to develop an internal capability for a framework for the internal state of the mechanism by inferring information captured through internal and external perceptions thirdly to conceptualise an artificially created pain classification in the form of synthetic pain which mimics the human concept of pain fourthly to demonstrate the implementation of synthetic pain activation on top of the robot framework using a reasoning approach in relation to past current and future predicted conditions lastly our aim is to develop and demonstrate an empathy function as a counter action to the kinds of synthetic pain being generated the framework allows robots to develop self consciousness by focusing attention on two primary levels of self namely subjective and objective once implemented we report the results and provide insights from novel experiments designed to measure whether a robot is capable of shifting its self consciousness using information obtained from exteroceptive and proprioceptive sensory perceptions we consider whether the framework can support reasoning skills that allow the robot to predict and generate an accurate pain acknowledgement and at the same time develop appropriate counter responses our experiments are designed to evaluate synthetic pain classification and the results show that the robot is aware of its internal state through the ability to predict its joint motion and produce appropriate artificial pain generation
